Homework 1

Matteo De Simone P38000232, Giacomo Caiazzo P38000236, Marco Bartone P38000237,
Nicola Monetti P38000238

Introduction

The following report documents the work conducted for Homework 1 of the Robotics Lab course. The objective of this assignment is to simulate the behavior of a 4-degree-of-freedom robotic manipulator in the Gazebo simulation environment, using ROS2. The document will be structured in sections, each presenting the steps followed to develop the different aspects of the homework.

1 Manipulator description and visualization in Rviz2

Using the terminal command "git clone," we downloaded the arm_description package, which contains the URDF and Stl files describing the manipulator. Once downloaded, we created a folder named "launch", which contains the launch file, named "display.launch.py", which loads the URDF and starts the robot_state_publisher node, the joint_state_publisher node, and the rviz2 node:

```

1
2  arm_description_path = get_package_share_directory('arm_description')
3
4  urdf_arm_description = os.path.join(arm_description_path, "urdf", "arm.urdf")
5
6
7
8  with open(urdf_arm_description, 'r') as infp:
9      link_desc = infp.read()
10
11  robot_description_links = {"robot_description": link_desc}
12
13
14
15  joint_state_publisher_node = Node(
16      package="joint_state_publisher_gui",
17      executable="joint_state_publisher_gui",
18  )
19
20  robot_state_publisher_node_links = Node(
21      package="robot_state_publisher", #ros2 run robot_state_publisher robot_state_publisher
22      executable="robot_state_publisher",
23      output="both",
24      parameters=[ robot_description_links,
25                  {"use_sim_time": True}],
26      remappings=[('/robot_description', '/robot_description')]
27  )
28
29
30
31  rviz_node = Node(
32      package="rviz2",
33      executable="rviz2",
34      name="rviz2",
35      output="log",
36      arguments=["-d", LaunchConfiguration("rviz_config_file")],
37  )
38
39  nodes_to_start = [
40      joint_state_publisher_node,
41      robot_state_publisher_node_links,
42      rviz_node
43  ]
44
45  return LaunchDescription(declared_arguments + nodes_to_start)

```

Figure 1: arm.urdf

Using the command "ros2 launch arm_description display.launch.py" we executed the launch file, which opened the Rviz2 screen containing the simulated model of the manipulator:

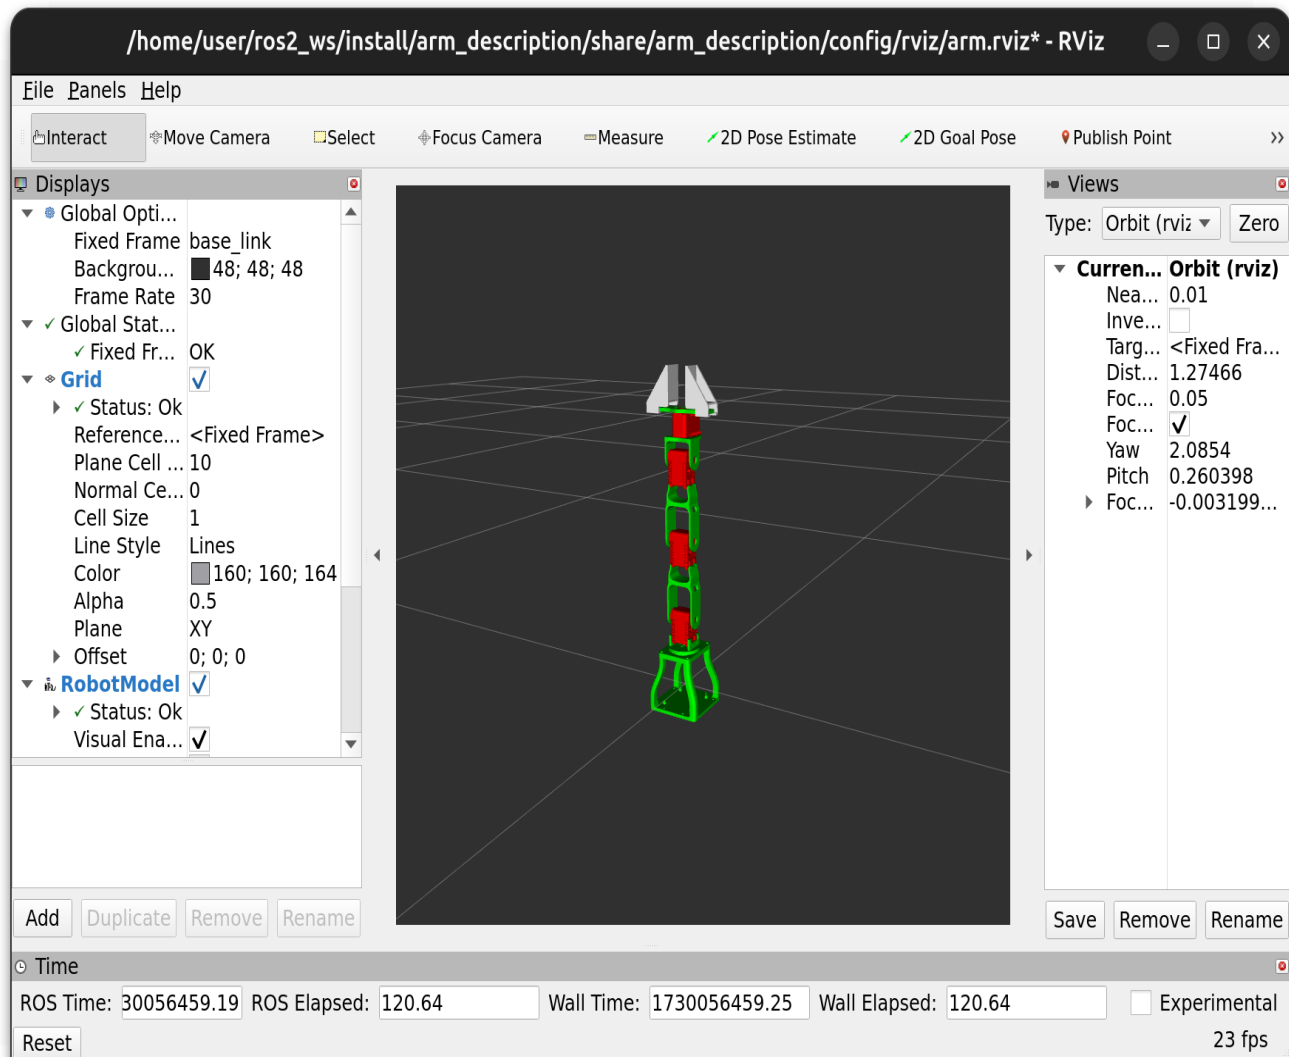

Figure 2: Rviz2 screen

The current rviz configuration has been saved in the `/config/rviz` folder as "arm.rviz", and can be loaded when rviz is launched with the following command:

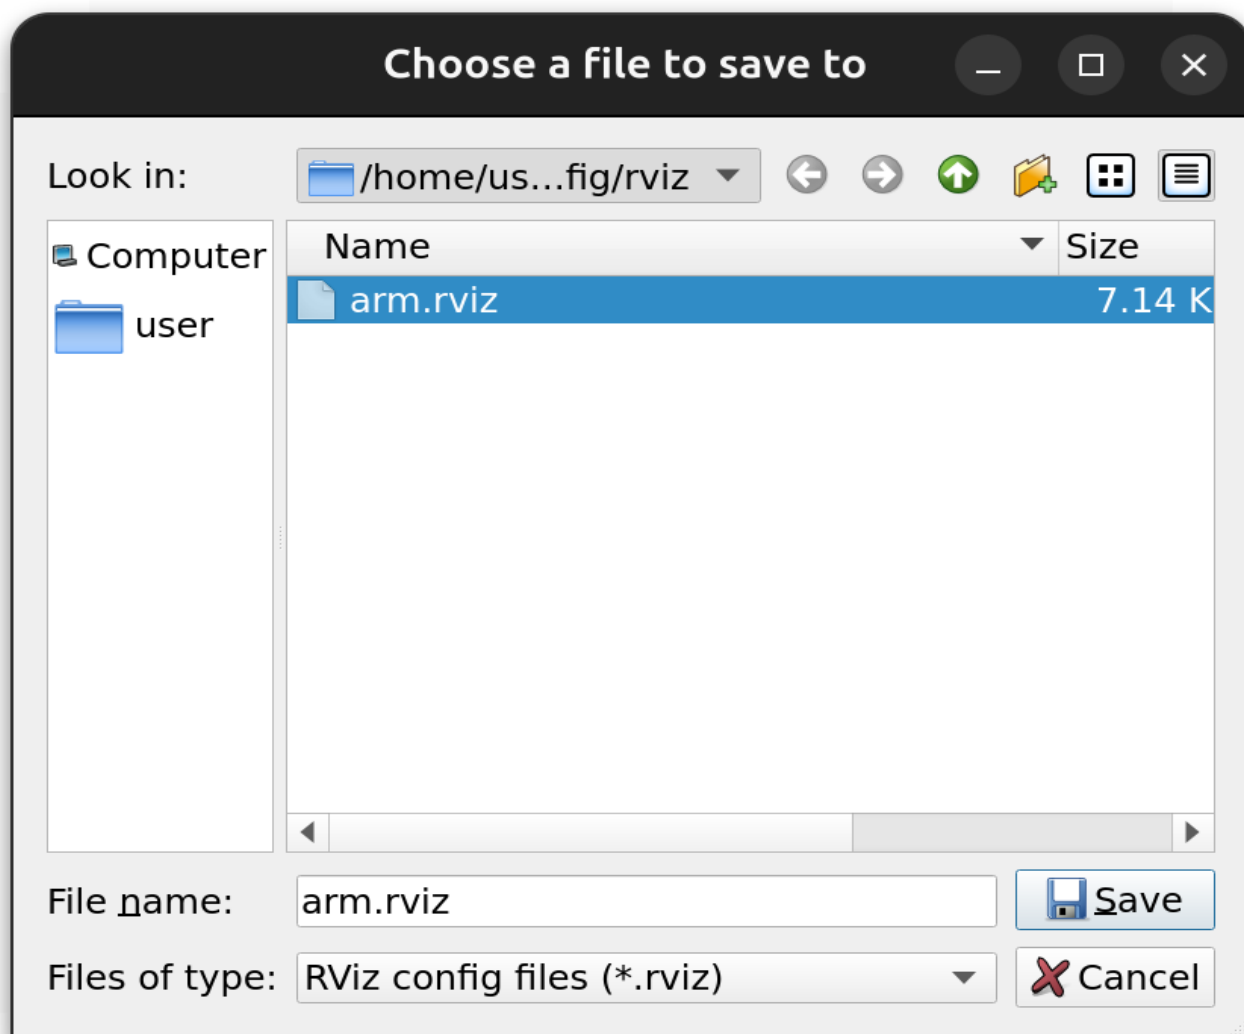

Figure 3: saving configuration

Below, we replaced the collision meshes of the manipulator in the URDF file using primitive shapes, specifically "box", modifying their dimensions to fit the elements of the manipulator:

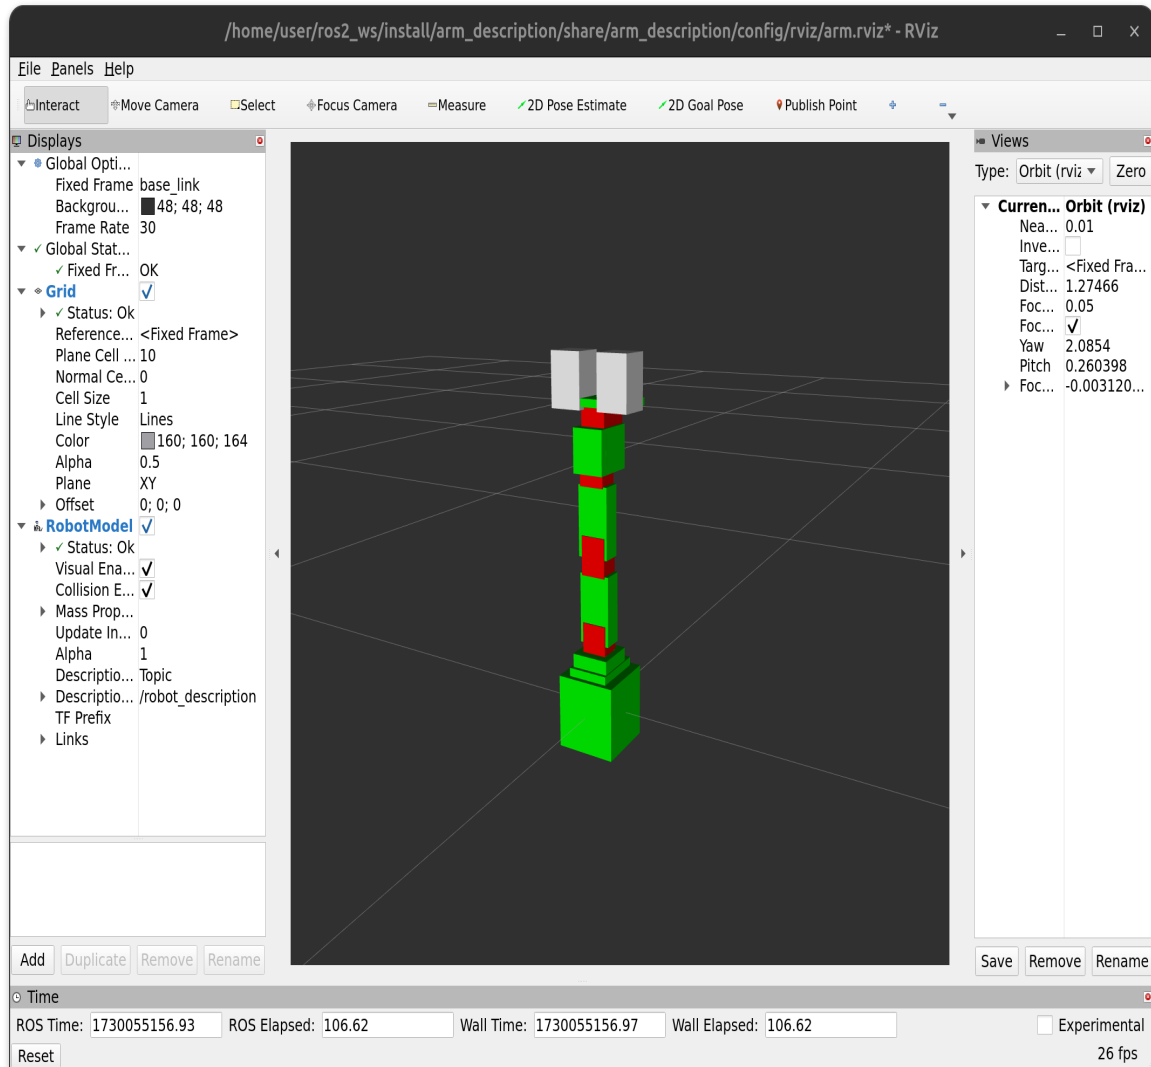

Figure 4: Rviz2 collision enabled

Some of these collision shapes were not centered with respect to the assigned elements, so the parameters related to the origin of these shapes, xyz, were modified:

```
1 <link name="base_turn">
2   <visual>
3     <geometry>
4       <mesh filename="package://arm_description/meshes/base_turn.stl" scale="0.001 0.001 0.001"/>
5     </geometry>
6     <origin rpy="0 0 0" xyz="0 0 0"/>
7     <material name="red"/>
8   </visual>
9   <collision>
10    <geometry>
11      <box size="0.065 0.08 0.012"/>
12    </geometry>
13    <origin rpy="0 0 0" xyz="0.0009 0.011 0.0025"/>
14  </collision>
15  <inertial>
16    <mass value="0.1"/>
17    <inertia ixx="1.35223008e+07" ixy="0.0" ixz="0.0" iyy="8.13814925e+06" iyz="0.0" izz="2.14903814e+07"/>
18  </inertial>
19 </link>
```

Figure 5: Collision shifted

2 Adding sensors and controllers and Gazebo visualization

An additional package, named `arm_gazebo`, has been created, which includes a launch file, `arm_world.launch.py`. This launch file is designed to load the URDF file and spawn the manipulator within the Gazebo simulation environment using the `create` node from the `ros_gz_sim` package:

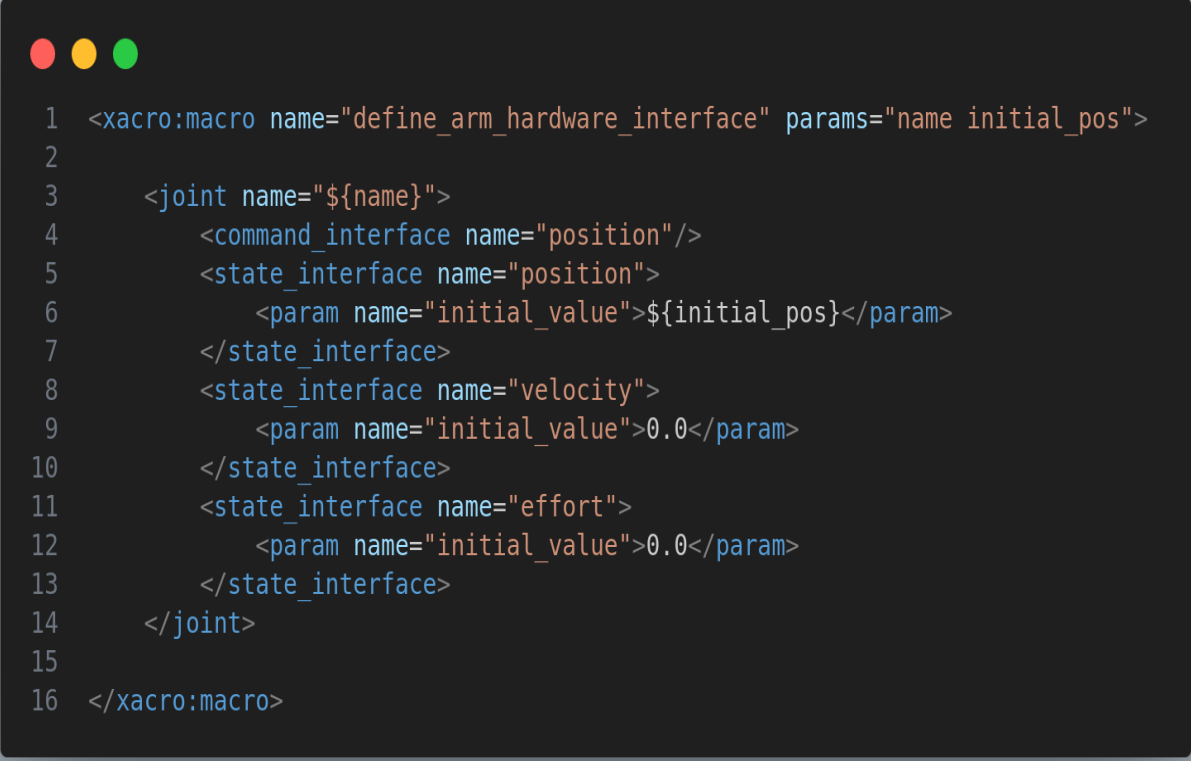

```

1  arm_description_path = get_package_share_directory('arm_description')
2
3  arm_gazebo_path = get_package_share_directory('arm_gazebo')
4
5  urdf_arm_gazebo = os.path.join(arm_description_path, "urdf", "arm.urdf")
6
7
8  with open(urdf_arm_gazebo_xacro, 'r') as infp:
9      link_desc = infp.read()
10
11  robot_description_links = {"robot_description": link_desc}
12
13
14
15  joint_state_publisher_node = Node(
16      package="joint_state_publisher_gui",
17      executable="joint_state_publisher_gui",
18  )
19
20  robot_state_publisher_node_links = Node(
21      package="robot_state_publisher", #ros2 run robot_state_publisher robot_state_publisher
22      executable="robot_state_publisher",
23      output="both",
24      parameters=[robot_description_links,
25                  {"use_sim_time": True}],
26  ),
27  remappings=[('/robot_description', '/robot_description')]
28  )
29
30  declared_arguments.append(DeclareLaunchArgument('gz_args', default_value='-r -v 1 empty.sdf',
31      description='Arguments for gz_sim'),)
32
33  gazebo_ignition = IncludeLaunchDescription(
34      PythonLaunchDescriptionSource(
35          [PathJoinSubstitution([FindPackageShare('ros_gz_sim'),
36              'launch',
37              'gz_sim.launch.py'])]),
38      launch_arguments={'gz_args': LaunchConfiguration('gz_args')}.items()
39  )
40
41  position = [0.0, 0.0, 0.033]
42
43  gz_spawn_entity = Node(
44      package='ros_gz_sim',
45      executable='create',
46      output='screen',
47      arguments=['-topic', 'robot_description',
48          '-name', 'arm',
49          '-allow_renaming', 'true',
50          "-x", str(position[0]),
51          "-y", str(position[1]),
52          "-z", str(position[2]),],
53  )
54
55
56  ign = [gazebo_ignition, gz_spawn_entity]
57
58  nodes_to_start = [
59      joint_state_publisher_node,
60      robot_state_publisher_node_links,
61      *ign
62  ]

```

Figure 6: `arm_world.launch.py`

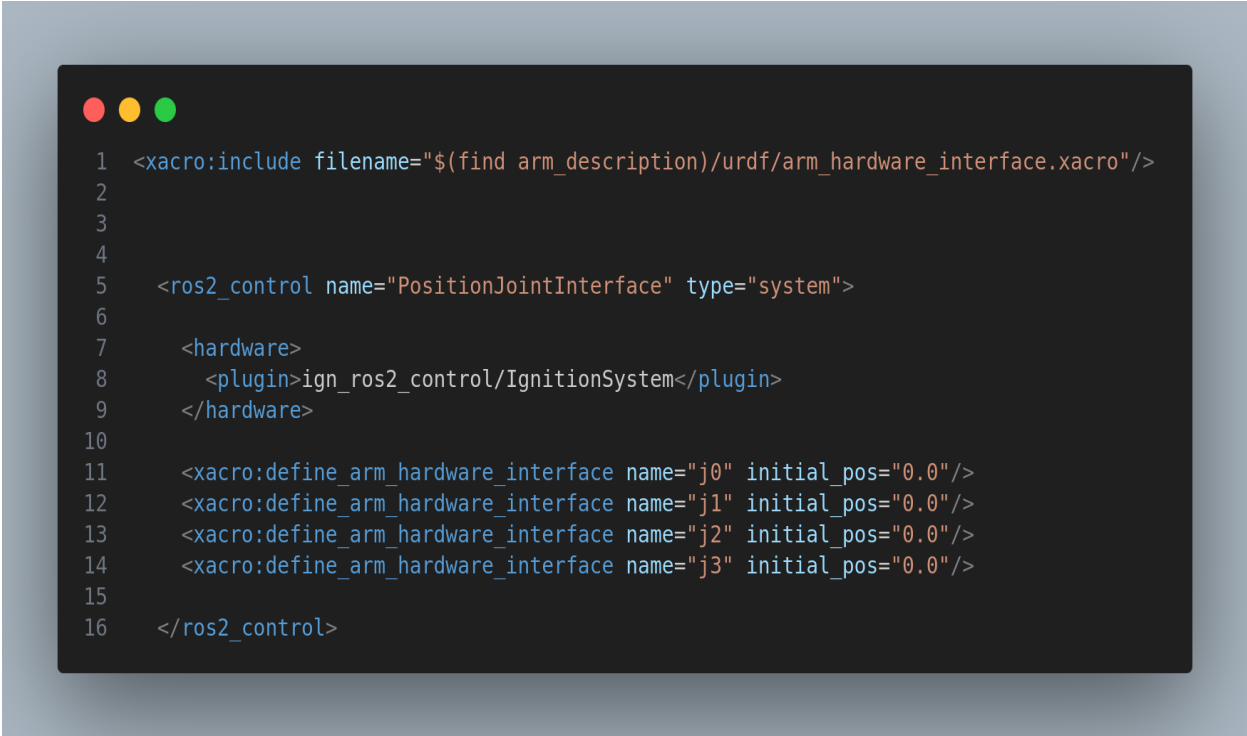

In order to equip the manipulator with a hardware interface named `PositionJointInterface`, a `xacro` macro has been developed:

A code editor window with a dark background and light-colored text. It displays a `xacro` macro definition for an arm hardware interface. The code is numbered from 1 to 16 on the left side. The macro is named `define_arm_hardware_interface` and takes two parameters: `name` and `initial_pos`. It defines a joint with the given name, which includes a `command_interface` for position, and three `state_interfaces` for position, velocity, and effort. Each state interface has an `initial_value` parameter. The `initial_value` for position is `initial_pos`, and for velocity and effort, it is `0.0`.

```
1 <xacro:macro name="define_arm_hardware_interface" params="name initial_pos">
2
3   <joint name="${name}">
4     <command_interface name="position"/>
5     <state_interface name="position">
6       <param name="initial_value">${initial_pos}</param>
7     </state_interface>
8     <state_interface name="velocity">
9       <param name="initial_value">0.0</param>
10    </state_interface>
11    <state_interface name="effort">
12      <param name="initial_value">0.0</param>
13    </state_interface>
14  </joint>
15
16 </xacro:macro>
```

Figure 7: `arm_hardware.xacro`

The xacro requires each joint, identified by the parameter name, to have an initial position and an initial velocity. In the case being examined, only the initial position is specified, therefore, it is treated as a parameter provided by the calling file, while the initial velocity is set to zero. This is made possible by the `command_interface`, which allows for the specification of position and velocity commands. Additionally, the xacro includes a `state_interface`, which enables the detection of the joint's state. The xacro thus constructed can be included in the URDF file as shown:

```

1 <xacro:include filename="$(find arm_description)/urdf/arm_hardware_interface.xacro"/>
2
3
4
5 <ros2_control name="PositionJointInterface" type="system">
6
7   <hardware>
8     <plugin>ign_ros2_control/IgnitionSystem</plugin>
9   </hardware>
10
11   <xacro:define_arm_hardware_interface name="j0" initial_pos="0.0"/>
12   <xacro:define_arm_hardware_interface name="j1" initial_pos="0.0"/>
13   <xacro:define_arm_hardware_interface name="j2" initial_pos="0.0"/>
14   <xacro:define_arm_hardware_interface name="j3" initial_pos="0.0"/>
15
16 </ros2_control>

```

Figure 8: `ros2_control`

The `ros2_control` framework provides a range of hardware interface types that can be used to create hardware components for specific robots or devices. Lines 444-447 reference the xacro for each of the four joints, passing the name and position as parameters.

It is important to note that a xacro macro cannot be called from a URDF file. To overcome this limitation, the physical and geometric description of the manipulator has been transferred to a `urdf.xacro` file. Subsequently, to load the robot in Gazebo, a conversion from `urdf.xacro` to `.urdf` has been implemented within `arm_world.launch.py`:

```

1 urdf_arm_gazebo_xacro = os.path.join(arm_description_path, "urdf", "arm.urdf.xacro")
2
3 with open(urdf_arm_gazebo_xacro, 'r') as infp:
4     link_desc = infp.read()
5
6 robot_description_links = {"robot_description": link_desc}
7
8 r_d_x = {"robot_description": Command(['xacro ', urdf_arm_gazebo_xacro])}
9
10 joint_state_publisher_node = Node(
11     package="joint_state_publisher_gui",
12     executable="joint_state_publisher_gui",
13 )
14
15 robot_state_publisher_node_links = Node(
16     package="robot_state_publisher", #ros2 run robot_state_publisher robot_state_publisher
17     executable="robot_state_publisher",
18     output="both",
19     parameters=[r_d_x,
20                 {"use_sim_time": True},
21     ],
22     remappings=[('/robot_description', '/robot_description')]
23 )

```

Figure 9: input via xacro

Once the hardware interface has been correctly set up, it's necessary to launch the controller_manager node using the following:

```

1 <gazebo>
2   <plugin filename="ign_ros2_control-system" name="ign_ros2_control::IgnitionROS2ControlPlugin">
3     <parameters>$(find arm_description)/config/arm_controllers.yaml</parameters>
4     <controller_manager_prefix_node_name>controller_manager</controller_manager_prefix_node_name>
5   </plugin>
6 </gazebo>

```

Figure 10: control manager

To correctly set up the controller_manager a yaml configuration file is needed. At this point, through the Gazebo simulation, it's possible to observe the difference between the actuated and non actuated robot:

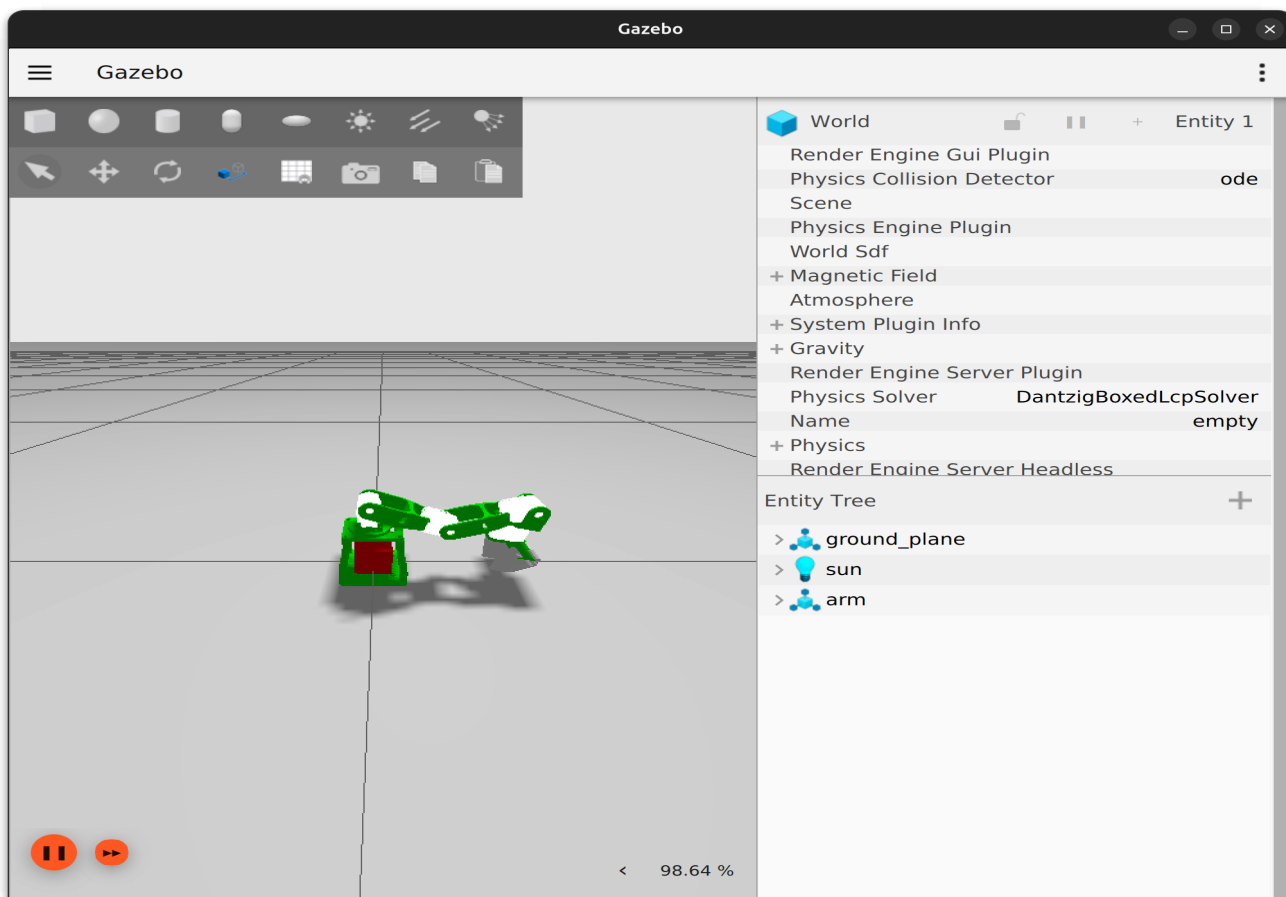

Figure 11: Manipulator without control manager active

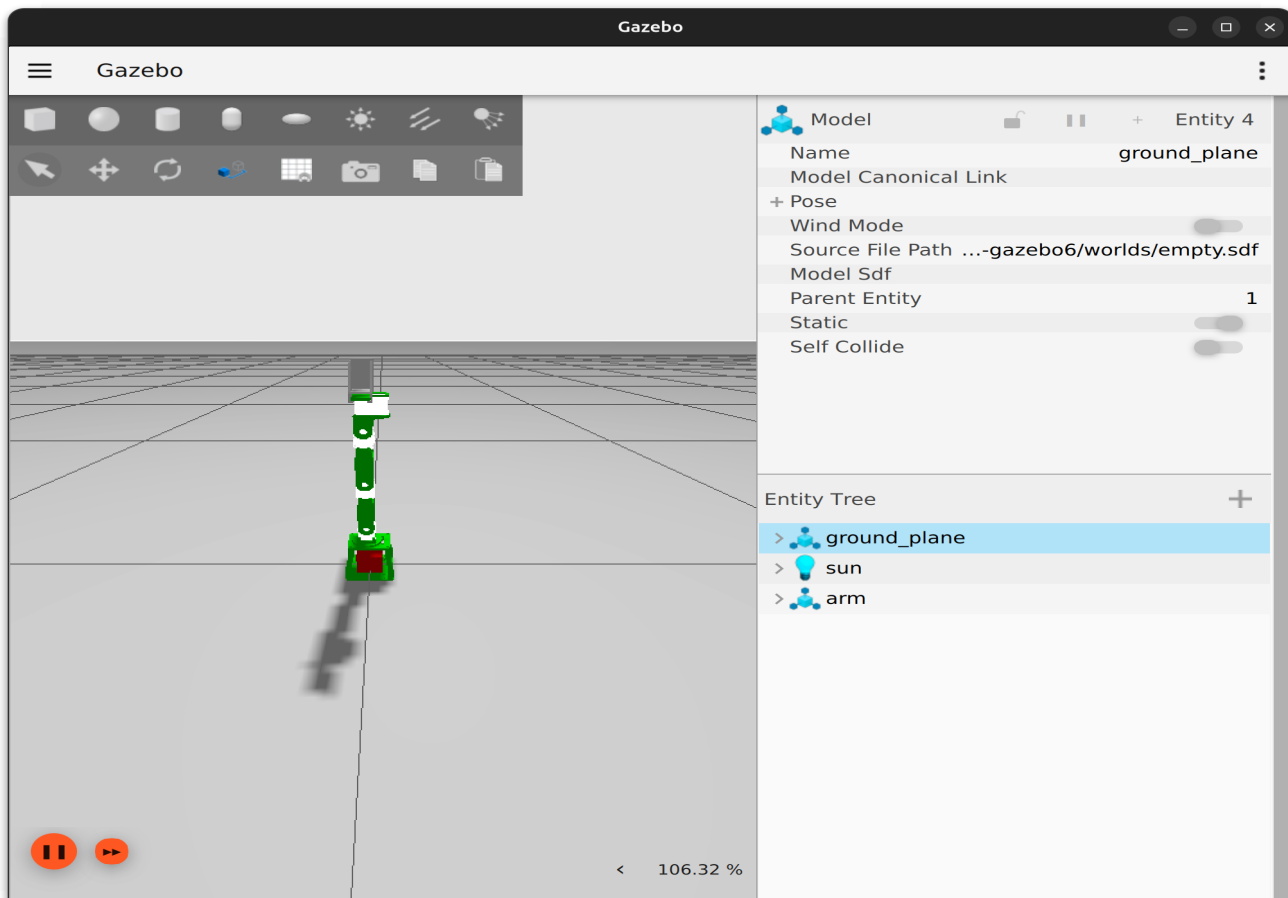

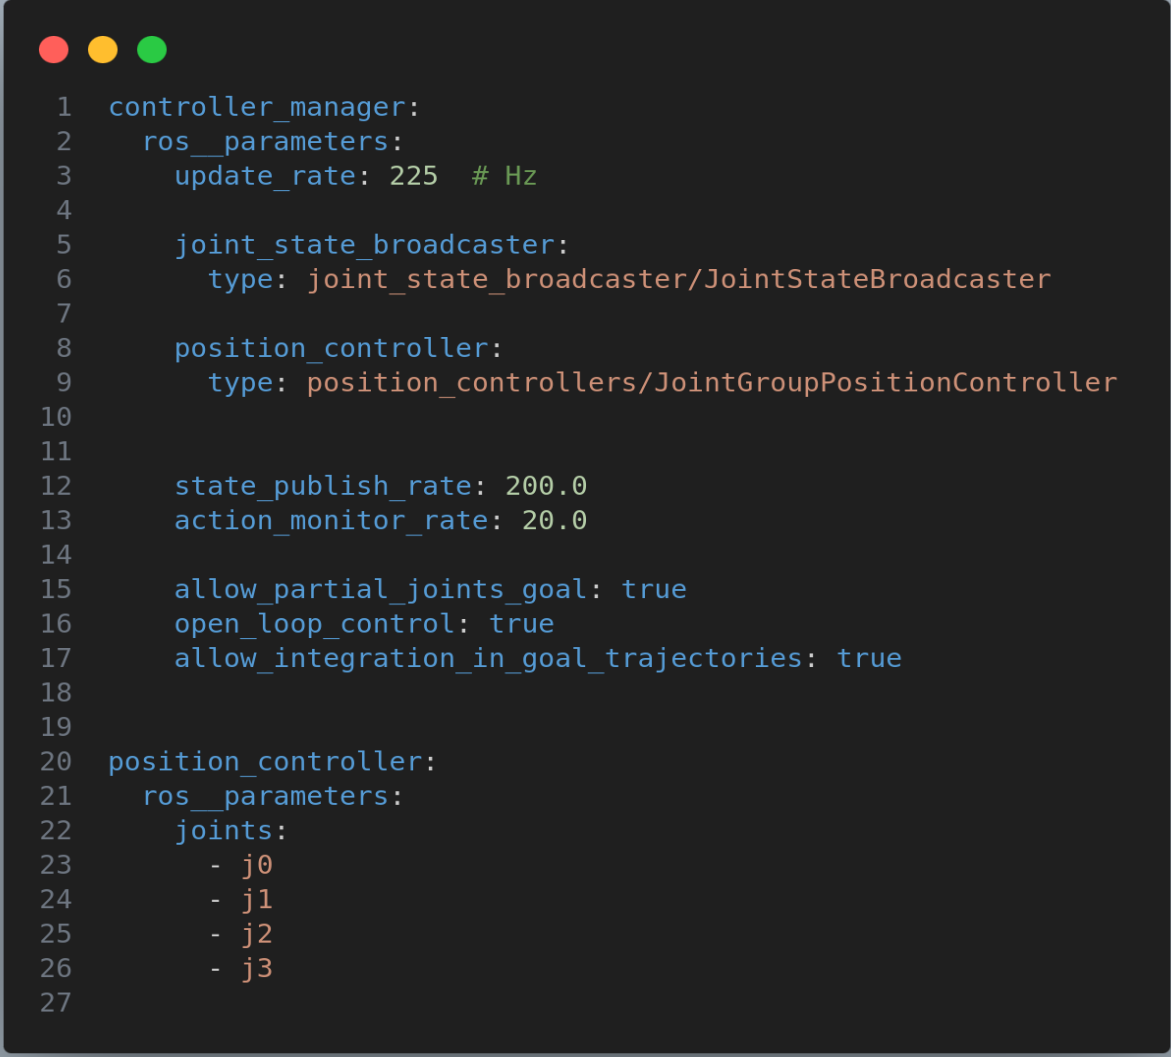

Figure 12: Manipulator with control manager active

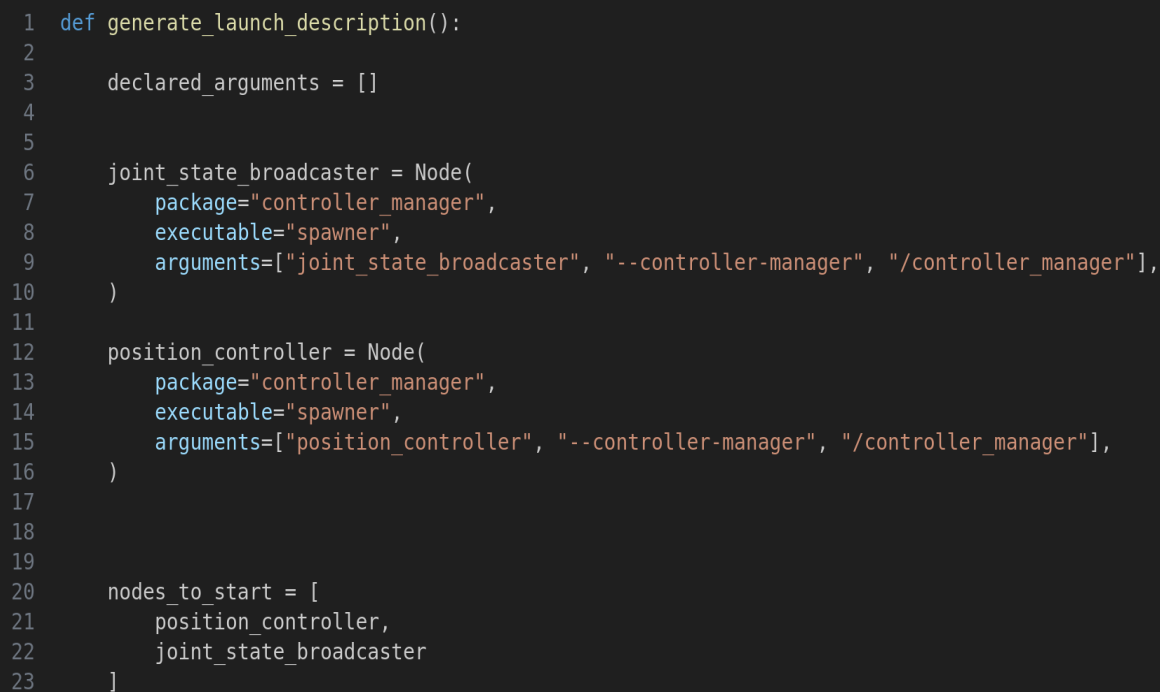

In order to actively control robot's position, the `joint_position_controller` has been defined, specifying in the yaml file as `ros__parameters` the four revolute joints. The same procedure needs to be carried out in order to add the `joint_state_broadcaster`:

```
1  controller_manager:
2    ros__parameters:
3      update_rate: 225  # Hz
4
5      joint_state_broadcaster:
6        type: joint_state_broadcaster/JointStateBroadcaster
7
8      position_controller:
9        type: position_controllers/JointGroupPositionController
10
11
12      state_publish_rate: 200.0
13      action_monitor_rate: 20.0
14
15      allow_partial_joints_goal: true
16      open_loop_control: true
17      allow_integration_in_goal_trajectories: true
18
19
20 position_controller:
21   ros__parameters:
22     joints:
23       - j0
24       - j1
25       - j2
26       - j3
27
```

Figure 13: file `controller.yaml`

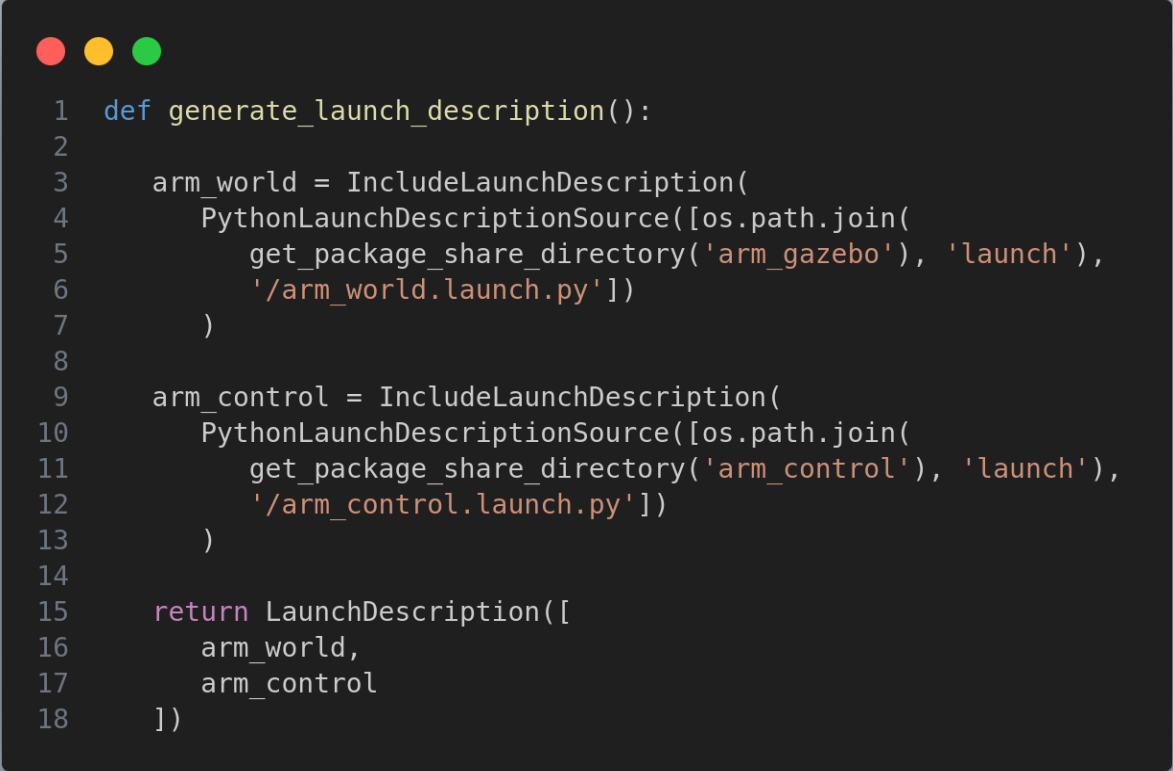

The final step is to create a `arm_control.launch.py` file which contains the instructions to launch the `joint_state_broad` and `joint_position_controller` nodes:

```
1 def generate_launch_description():
2
3     declared_arguments = []
4
5
6     joint_state_broadcaster = Node(
7         package="controller_manager",
8         executable="spawner",
9         arguments=["joint_state_broadcaster", "--controller-manager", "/controller_manager"],
10    )
11
12    position_controller = Node(
13        package="controller_manager",
14        executable="spawner",
15        arguments=["position_controller", "--controller-manager", "/controller_manager"],
16    )
17
18
19
20    nodes_to_start = [
21        position_controller,
22        joint_state_broadcaster
23    ]
```

Figure 14: `arm_control.launch.py`

In order to ease the execution of the whole project a `arm_gazebo.launch.py` file has been written including both the `arm_world.launch.py` and `arm_control.launch.py` files:

```
1 def generate_launch_description():
2
3     arm_world = IncludeLaunchDescription(
4         PythonLaunchDescriptionSource([os.path.join(
5             get_package_share_directory('arm_gazebo'), 'launch'),
6             '/arm_world.launch.py'])
7     )
8
9     arm_control = IncludeLaunchDescription(
10        PythonLaunchDescriptionSource([os.path.join(
11            get_package_share_directory('arm_control'), 'launch'),
12            '/arm_control.launch.py'])
13    )
14
15    return LaunchDescription([
16        arm_world,
17        arm_control
18    ])
```

Figure 15: `arm_gazebo.launch.py`

3 Adding a camera sensor to the robot

The first step to add a camera sensor to the robot manipulator was creating a camera link connected to the base link, through to a fixed camera joint:

```
1 <joint name="camera_joint" type="fixed">
2   <parent link="base_link"/>
3   <child link="camera_link"/>
4   <origin xyz="0.0 0.0 0.0"/>
5 </joint>
6
7 <link name="camera_link">
8   <visual>
9     <geometry>
10      <box size="0.05 0.05 0.05"/>
11    </geometry>
12    <origin rpy="0 0 0" xyz="0 0 0"/>
13    <material name="red">
14      <color rgba="1 0 0 1"/>
15    </material>
16  </visual>
17  <collision>
18    <geometry>
19      <box size="0.05 0.05 0.05"/>
20    </geometry>
21    <origin rpy="0 0 0" xyz="0 0 0"/>
22  </collision>
23 </link>
```

Figure 16: camera_link in urdf.xacro

In order to effectively set up the sensor it's necessary write a `arm_camera.xacro` which attaches the camera sensor to the camera link using the `gz-sim-sensors-system` plugin:

```

1  <xacro:macro name="arm_camera" params="reference">
2
3      <gazebo>
4          <plugin filename="gz-sim-sensors-system" name="gz::sim::systems::Sensors">
5              <render_engine>ogre2</render_engine>
6          </plugin>
7      </gazebo>
8
9      <gazebo reference="${reference}">
10         <sensor name="camera" type="camera">
11             <camera>
12                 <horizontal_fov>1.047</horizontal_fov>
13                 <image>
14                     <width>320</width>
15                     <height>240</height>
16                 </image>
17                 <clip>
18                     <near>0.1</near>
19                     <far>100</far>
20                 </clip>
21             </camera>
22             <always_on>1</always_on>
23             <update_rate>30</update_rate>
24             <visualize>true</visualize>
25             <topic>camera</topic>
26         </sensor>
27     </gazebo>
28
29
30 </xacro:macro>

```

Figure 17: `arm_camera.xacro`

```

1  <xacro:include filename="$(find arm_description)/urdf/arm_camera.xacro"/>
2
3      <xacro:arm_camera reference="camera_link"/>
4

```

Figure 18: camera in `urdf.xacro`

It's now possible to appreciate the camera point of view using the Gazebo simulation and `rqt_image_view`:

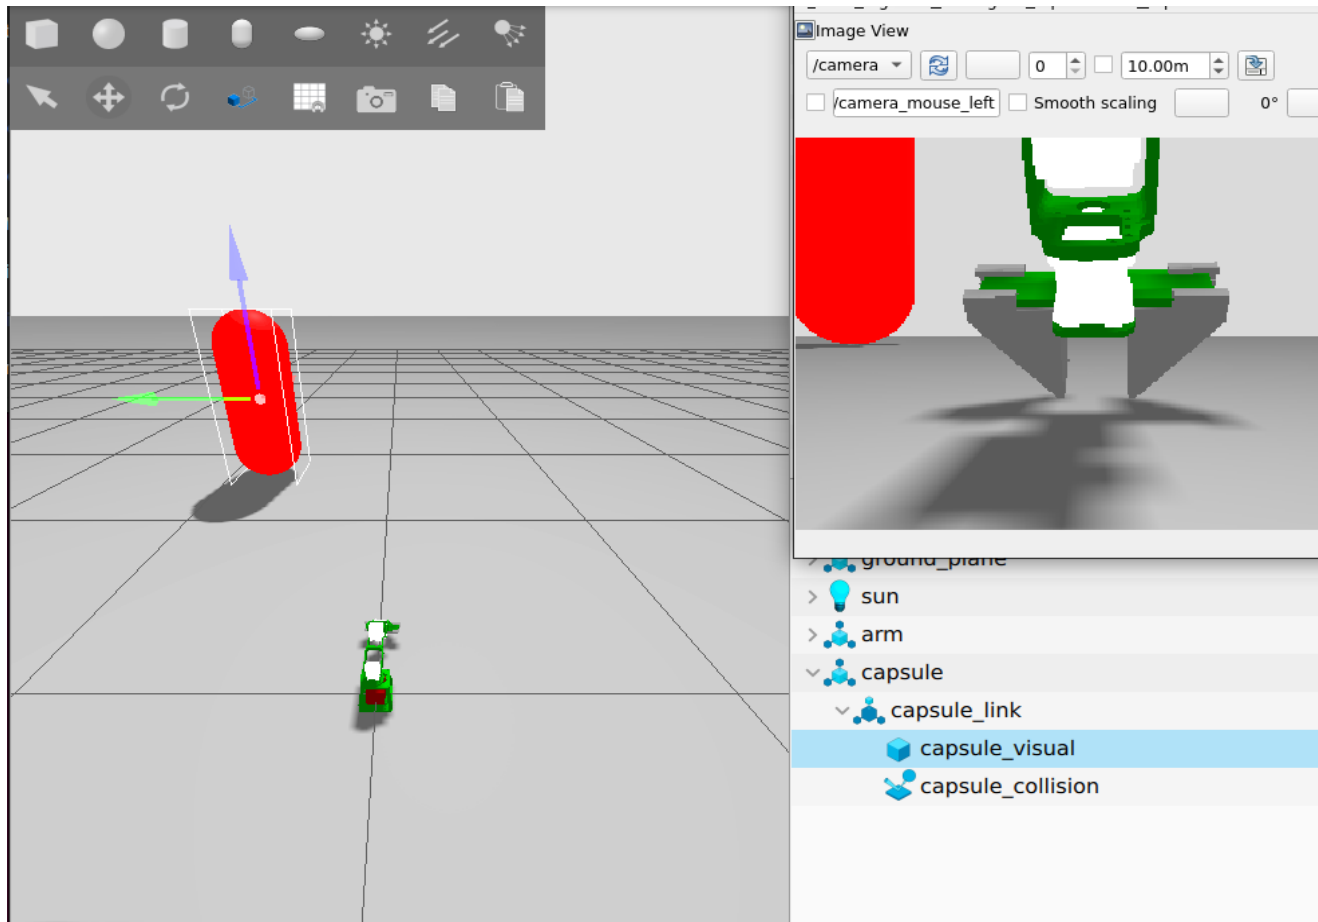

Figure 19: camera point of view

4 Adding a ROS publisher node

Inside the `arm_control` package, we created a ROS C++ node called `arm_controller_node.cpp`, which includes a publisher that writes commands to the `/position_controller/commands` topic via keyboard input, and a subscriber to the `/joint_states` topic that prints the current position of the joints:

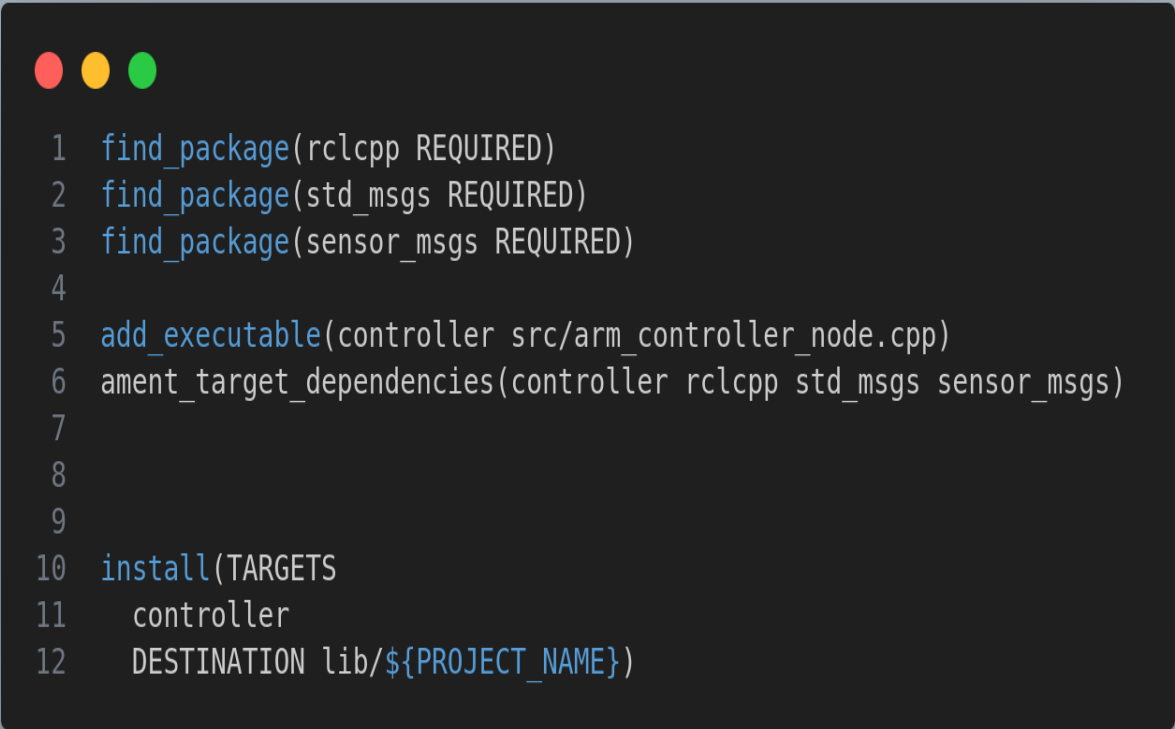

```

1  class Controller : public rclcpp::Node
2  {
3  public:
4      Controller()
5      : Node("controller")
6      {
7
8          values_.resize(4);
9
10         std::cout << "Enter " << "4" << " elements:\n";
11         std::cin >> values_[0] >> values_[1] >> values_[2] >> values_[3];
12
13         // Cambia il tipo del publisher
14         publisher_ = this->create_publisher<std_msgs::msg::Float64MultiArray>("/position_controller/commands", 10);
15
16         // Timer che chiama timer callback ogni 500 ms
17         timer_ = this->create_wall_timer(
18             500ms, std::bind(&Controller::timer_callback, this));
19
20         // Cambia il tipo della subscription a Float64MultiArray
21         subscription_ = this->create_subscription<sensor_msgs::msg::JointState>(
22             "/joint_states", 10, std::bind(&Controller::topic_callback, this, _1));
23     }
24
25 private:
26     void timer_callback()
27     {
28         // Crea un oggetto Float64MultiArray
29         auto message = std_msgs::msg::Float64MultiArray();
30         // Popola l'array con dei valori (ad esempio, valori incrementali)
31         for (size_t i = 0; i < 4; ++i) {
32             message.data.push_back(static_cast<double>(values_[i])); // Aggiungi valori all'array
33         }
34
35         // Pubblica il messaggio
36         publisher_>publish(message);
37     }
38
39     // Modifica del tipo di parametro nel callback
40     void topic_callback(const sensor_msgs::msg::JointState & message) const
41     {
42         // Logga i valori ricevuti
43         RCLCPP_INFO(this->get_logger(), "position: [%2f, %2f, %2f, %2f]", message.position[0], message.position[1], message.position[2], message.position[3]);
44     }
45
46     // Cambia il tipo della subscription
47     rclcpp::Subscription<sensor_msgs::msg::JointState>::SharedPtr subscription_;
48     rclcpp::TimerBase::SharedPtr timer_;
49     rclcpp::Publisher<std_msgs::msg::Float64MultiArray>::SharedPtr publisher_;
50     std::vector<float> values_;
51 };

```

Figure 20: Controller node class

To ensure it was recognized, dependencies were added to the CMakeLists.txt file, specifically rclcpp, sensor_msgs, and std_msgs:

```
1 find_package(rclcpp REQUIRED)
2 find_package(std_msgs REQUIRED)
3 find_package(sensor_msgs REQUIRED)
4
5 add_executable(controller src/arm_controller_node.cpp)
6 ament_target_dependencies(controller rclcpp std_msgs sensor_msgs)
7
8
9
10 install(TARGETS
11     controller
12     DESTINATION lib/${PROJECT_NAME})
```

Figure 21: dependencies in CMakeLists.txt
